

AdvanceDevops Experiment 4

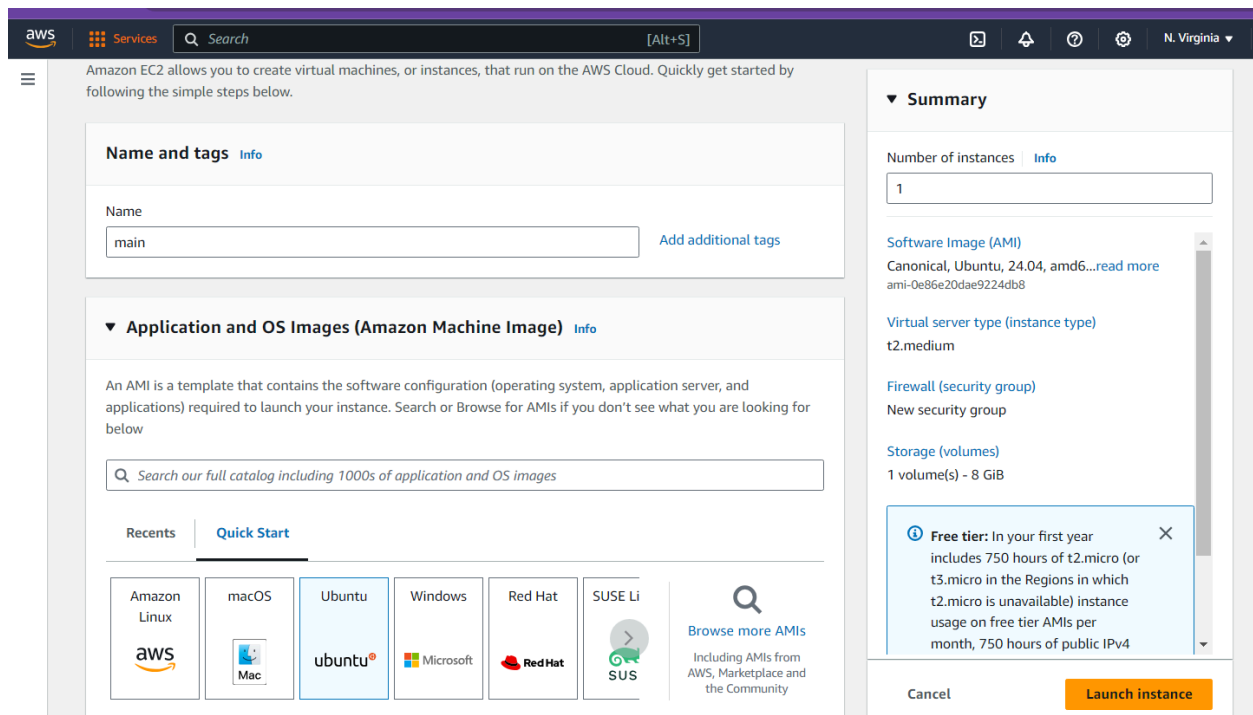

Aim: To install Kubectl and execute Kubectl commands to manage the Kubernetes cluster and deploy Your First Kubernetes Application.

Theory:

Kubernetes, originally developed by Google, is an open-source container orchestration platform. It automates the deployment, scaling, and management of containerized applications, ensuring high availability and fault tolerance. Kubernetes is now the industry standard for container orchestration and is governed by the **Cloud Native Computing Foundation (CNCF)**, with contributions from major cloud and software providers like Google, AWS, Microsoft, IBM, Intel, Cisco, and Red Hat.

Kubernetes Deployment: Is a resource in Kubernetes that provides declarative updates for Pods and ReplicaSets. With a Deployment, you can define how many replicas of a pod should run, roll out new versions of an application, and roll back to previous versions if necessary. It ensures that the desired number of pod replicas are running at all times.

Step 1: Log in to your AWS Academy/personal account and launch a new Ec2 Instance. Select Ubuntu as AMI and t2.medium as Instance Type, create a key of type RSA with .pem extension, and move the downloaded key to the new folder.

▼ Instance type [Info](#) | [Get advice](#)

Instance type

t2.medium
Family: t2 2 vCPU 4 GiB Memory Current generation: true
On-Demand Linux base pricing: 0.0464 USD per Hour
On-Demand RHEL base pricing: 0.0752 USD per Hour
On-Demand Windows base pricing: 0.0644 USD per Hour
On-Demand SUSE base pricing: 0.1464 USD per Hour

☐ All generations
[Compare instance types](#)

Additional costs apply for AMIs with pre-installed software

▼ Key pair (login) [Info](#)

You can use a key pair to securely connect to your instance. Ensure that you have access to the selected key pair before you launch the instance.

Key pair name - *required*

Exp4

[Create new key pair](#)

▼ Network settings [Info](#)

Network [Info](#)

Edit

▼ Summary

Number of instances [Info](#)

1

Software Image (AMI)

Canonical, Ubuntu, 24.04, amd64...[read more](#)

ami-0e86e20dae9224db8

Virtual server type (instance type)

t2.medium

Firewall (security group)

New security group

Storage (volumes)

1 volume(s) - 8 GiB

Free tier: In your first year includes 750 hours of t2.micro (or t3.micro in the Regions in which t2.micro is unavailable) instance usage on free tier AMIs per month, 750 hours of public IPv4

Cancel

Launch instance

Step 2: After creating the instance click on Connect the instance and navigate to SSH Client.

Instances (1) Info									
<div> <div>Find Instance by attribute or tag (case-sensitive)</div> <div>All states</div> </div>									
<input type="checkbox"/>	Name	Instance ID	Instance state	Instance type	Status check	Alarm status	Availability Zone	Public IPv4 DNS	Public
<input type="checkbox"/>	main	i-045e45a4940c82f2b	Running	t2.medium	2/2 checks passed	View alarms	us-east-1c	ec2-54-89-80-249.com...	54.89

[EC2](#) > [Instances](#) > [i-0c58e4cedc38ab19c](#) > [Connect to instance](#)

Connect to instance [Info](#)

Connect to your instance i-0c58e4cedc38ab19c (main1) using any of these options

EC2 Instance Connect

Session Manager

SSH client

EC2 serial console

Instance ID

i-0c58e4cedc38ab19c (main1)

- Open an SSH client.
- Locate your private key file. The key used to launch this instance is Exp4.pem
- Run this command, if necessary, to ensure your key is not publicly viewable.

```
chmod 400 "Exp4.pem"
```
- Connect to your instance using its Public DNS:

```
ec2-107-22-62-86.compute-1.amazonaws.com
```

Example:

```
ssh -i "Exp4.pem" ubuntu@ec2-107-22-62-86.compute-1.amazonaws.com
```

Note: In most cases, the guessed username is correct. However, read your AMI usage instructions to check if the AMI owner has changed the default AMI username.

Cancel

Step 3: Now open the folder in the terminal where our .pem key is stored and paste the Example command (starting with ssh -i) in the terminal.

Run the below commands to install and setup Docker.

```
curl -fsSL https://download.docker.com/linux/ubuntu/gpg | sudo apt-key add -  
curl -fsSL https://download.docker.com/linux/ubuntu/gpg | sudo tee  
/etc/apt/trusted.gpg.d/docker.gpg > /dev/null
```

```
sudo add-apt-repository "deb [arch=amd64] https://download.docker.com/linux/ubuntu  
$(lsb_release -cs) stable"
```

```
ubuntu@ip-172-31-92-253:~$ curl -fsSL https://download.docker.com/linux/ubuntu/gpg | sudo apt-key add -  
curl -fsSL https://download.docker.com/linux/ubuntu/gpg | sudo tee /etc/apt/trusted.gpg.d/docker.gpg  
> /dev/null  
sudo add-apt-repository "deb [arch=amd64] https://download.docker.com/linux/ubuntu $(lsb_release -cs)  
stable"  
Warning: apt-key is deprecated. Manage keyring files in trusted.gpg.d instead (see apt-key(8)).  
OK

```

```

tificate and key
[addons] Applied essential addon: CoreDNS
[addons] Applied essential addon: kube-proxy

Your Kubernetes control-plane has initialized successfully!

To start using your cluster, you need to run the following as a regular user:

  mkdir -p $HOME/.kube
  sudo cp -i /etc/kubernetes/admin.conf $HOME/.kube/config
  sudo chown $(id -u):$(id -g) $HOME/.kube/config

Alternatively, if you are the root user, you can run:

  export KUBECONFIG=/etc/kubernetes/admin.conf

You should now deploy a pod network to the cluster.
Run "kubectl apply -f [podnetwork].yaml" with one of the options listed at:
  https://kubernetes.io/docs/concepts/cluster-administration/addons/

Then you can join any number of worker nodes by running the following on each as root:

kubeadm join 172.31.92.253:6443 --token 90n342.w0y0ehbtppbqeocz \
  --discovery-token-ca-cert-hash sha256:072239c6fcbdd2b8842bd4badd167478379f455ddc7525f46bb5902
87f594319

```

Copy the mkdir and chown commands from the top and execute them.

```

mkdir -p $HOME/.kube
sudo cp -i /etc/kubernetes/admin.conf $HOME/.kube/config
sudo chown $(id -u):$(id -g) $HOME/.kube/config

```

```

ubuntu@ip-172-31-92-253:~$ mkdir -p $HOME/.kube
sudo cp -i /etc/kubernetes/admin.conf $HOME/.kube/config
sudo chown $(id -u):$(id -g) $HOME/.kube/config

```

Add a common networking plugin called flannel as mentioned in the code.

kubectl apply -f

<https://raw.githubusercontent.com/coreos/flannel/master/Documentation/kube-flannel.yml>

```

ubuntu@ip-172-31-92-253:~$ kubectl apply -f https://raw.githubusercontent.com/coreos/flannel/master/Documentation/kube-flannel.yml
namespace/kube-flannel created
clusterrole.rbac.authorization.k8s.io/flannel created
clusterrolebinding.rbac.authorization.k8s.io/flannel created
serviceaccount/flannel created
configmap/kube-flannel-cfg created
daemonset.apps/kube-flannel-ds created

```

Step 7: Now that the cluster is up and running, we can deploy our nginx server on this cluster. Apply this deployment file using this command to create a deployment

kubectl apply -f <https://k8s.io/examples/application/deployment.yaml>

```

daemonset.apps/nginx-daemonset created
ubuntu@ip-172-31-92-253:~$ kubectl apply -f https://k8s.io/examples/application/deployment.yaml
deployment.apps/nginx-deployment created

```

kubectl get pods

```

ubuntu@ip-172-31-92-253:~$ kubectl get pods
NAME                                READY   STATUS    RESTARTS   AGE
nginx-deployment-d556bf558-llw22    0/1     Pending   0           25s

```

get pods

```

ubuntu@ip-172-31-92-253:~$ kubectl get pods
NAME                                READY   STATUS    RESTARTS   AGE
nginx-deployment-d556bf558-llw22    1/1     Running   0           11m
nginx-deployment-d556bf558-xbpvn    1/1     Running   0           11m

```

POD_NAME=\$(kubectl get pods -l app=nginx -o jsonpath="{.items[0].metadata.name}")

kubectl port-forward \$POD_NAME 8080:80

```

ubuntu@ip-172-31-92-253:~$ POD_NAME=$(kubectl get pods -l app=nginx -o jsonpath="{.items[0].metadata.name}")
ubuntu@ip-172-31-92-253:~$ kubectl port-forward $POD_NAME 8080:80
Forwarding from 127.0.0.1:8080 -> 80
Forwarding from [::1]:8080 -> 80
Handling connection for 8080

```

Step 8: Verify your deployment

Open up a new terminal and ssh to your EC2 instance.

Then, use this curl command to check if the Nginx server is running.

curl --head http://127.0.0.1:8080

```
PS C:\Users\LENOVO> ssh -i "Exp4.pem" ubuntu@ec2-54-164-58-232.compute-1.amazonaws.com
Welcome to Ubuntu 24.04 LTS (GNU/Linux 6.8.0-1012-aws x86_64)

```

```
Last login: Wed Sep 25 16:12:02 2024 from 203.194.102.247
ubuntu@ip-172-31-92-253:~$ curl --head http://127.0.0.1:8080
HTTP/1.1 200 OK
Server: nginx/1.14.2
Date: Wed, 25 Sep 2024 16:45:49 GMT
Content-Type: text/html
Content-Length: 612
Last-Modified: Tue, 04 Dec 2018 14:44:49 GMT
Connection: keep-alive
ETag: "5c0692e1-264"
Accept-Ranges: bytes
```

If the response is 200 OK and you can see the Nginx server name, your deployment was successful.

We have successfully deployed our Nginx server on our EC2 instance.

Conclusion:

- 1. EC2 Instance Launch Issues:** Incorrect AMI Selection: Selecting the wrong Amazon Machine Image (AMI) could cause issues, especially if it doesn't support the required software for Kubernetes.
- 2. Kubernetes Installation Issues:** Installation Fails Due to Network Issues: Sometimes, the installation of Kubernetes can fail due to network errors or misconfigured package repositories.
- 3. Nginx Deployment Issues:** Nginx Server Not Running: After deploying Nginx, the server might not start due to insufficient resources on the EC2 instance or missing configurations.
